GANGLIO  
LINFÁTICO

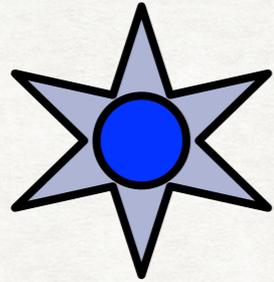

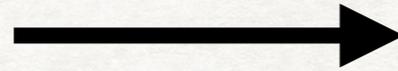

**FIGURE 2** | Langerhans cells (LCs) during inflammation. During the initial phase of inflammation, LCs migrate to the draining lymph node, but unlike conventional/classical dendritic cells (cDCs), LCs are observed to peak in number at day 4 after initial sensitization to antigen. The migration of LCs has been observed to be much slower. After 1 week, it is believed that inflammatory dendritic epidermal cells (IDECs) increase in number. These circulating blood monocytes from the bone marrow differentiate to LC-like cells and do not depend on transforming growth factor- $\beta$  (TGF- $\beta$ ) signaling pathway but are morphologically and phenotypically very similar to resident LCs. IDECs reside in the epidermal-dermal junction, and after 1 week of recruitment, they most likely migrate into the draining lymph node. These show the probable functional difference between LCs and IDECs as the kinetics of recruitment and migration between the two cells is different.

---

**ABSTRACT.** House dust mite (HDM) allergens are the most common allergens for induction of IgE-mediated hypersensitivity. Recently, epicutaneous sensitization with HDM allergens has been emphasized in the development of atopic dermatitis (AD) by producing various soluble factors in keratinocytes. Among the soluble factors, GM-CSF is a key molecule that activates Langerhans cells, antigen-presenting cells in the epidermis. In the present study, we investigated the effects of *Dermatophagoides farinae* (Der f) on GM-CSF production in a canine keratinocyte cell line, CPEK. CPEKs were found to produce GM-CSF upon stimulation by Der f. The GM-CSF production was suppressed by addition of a cysteine protease inhibitor. The present results suggest that cysteine protease-derived Der f may be an initiator of allergic inflammation by inducing the production of GM-CSF in keratinocytes.

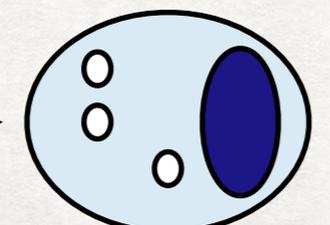

**KEY WORDS:** atopic dermatitis, canine, Der f, GM-CSF, keratinocytes.

#### Summary

Studies published in recent years have highlighted the role of epidermal barrier defects in both atopic skin disease and the development of broader allergic manifestations. While genetic determinants of barrier function are important, it is clear that local acquired effects are also involved in disease pathogenesis. In this review, we aimed to summarize the known influences of cytokines abundantly expressed during atopic skin disease on components of epidermal barrier integrity and function.

# TNF- $\alpha$ Downregulates Filaggrin and Loricrin through c-Jun N-terminal Kinase: Role for TNF- $\alpha$ Antagonists to Improve Skin Barrier

Byung Eui Kim<sup>1</sup>, Michael D. Howell<sup>1,2</sup>, Emma Guttman<sup>3,4</sup>, Patricia M. Gilleaudeau<sup>3</sup>, Irma R. Cardinale<sup>3</sup>, Mark Boguniewicz<sup>1,2</sup>, James G. Krueger<sup>3</sup> and Donald Y.M. Leung<sup>1,2</sup>

Filaggrin (*FLG*), loricrin (*LOR*), and involucrin are important epidermal barrier proteins. As psoriasis is characterized by overexpression of tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) and impaired skin barrier, we investigated the expression of skin barrier proteins in psoriasis patients and whether their expression was modulated by TNF- $\alpha$ . The expression of *FLG* and *LOR* was found to be decreased in lesional and non-lesional skin of psoriasis patients. A correlation was found between the expression of TNF- $\alpha$  and epidermal barrier proteins in psoriasis. TNF- $\alpha$  was found to modulate the expression of *FLG* and *LOR* via a c-Jun N-terminal kinase-dependent pathway. Importantly, we report that clinical treatment of psoriasis patients with a TNF- $\alpha$  antagonist results in significant enhancement of epidermal barrier protein expression. Our current study suggests that TNF inhibits barrier protein expression, and TNF- $\alpha$  antagonists may contribute to clinical improvement in patients with psoriasis by improving barrier protein expression.
